#4471 reviewed: two classified problems, not one

owner **Miehau with OpenAI coding assistant** investigated reviewed 2026-10-28 · 0 days ago

What the evidence shows

The original incident says one issue and one queued fix. Its own computed table contradicts that claim. The export contains overlapping pages: count report IDs once, not rows. Classify using the tenant's locale and booking form, not the browser locale or intake tag.

412 reports merged into #4471 · **2** causes

cause	reports	tagged as	tenants	seen	
`parser`	379	parser ×356 · hint ×23	11	2026-04-01 → 2026-10-04	#4471
`hint`	33	hint ×18 · parser ×15	3	2026-04-17 → 2026-09-22	**not this ticket — no ticket of its own**

5 reports read as a one-day move; filed under `parser` by tenant.

Separate engineering work

- **Parser:** the shared parser reads dates month first for day-first tenants. For example, R-41200 reports a 7 April reminder on 4 July. Correct the parser's date interpretation using the tenant's date convention. Check both app and email paths and ambiguous day/month input.
- **Hint:** booking-v3 prints MM/DD/YYYY for day-first tenants, but the form reads input in the tenant's convention. A person following the hint therefore enters the wrong order. Correct the hint to match the form's interpretation; changing only the shared parser does not fix this mismatch. Check booking-v3 form submissions separately from app/email reports and from booking-v2.

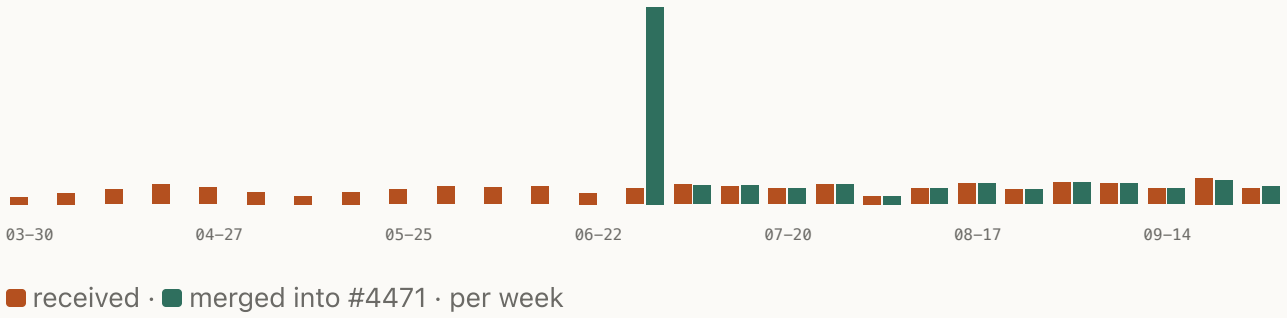

Each classified group needs its own issue. The table is the computed count for this export, not a live count of the desk today.

Limits: five reports need follow-up

The tenant/channel classifier places R-41202, R-41209, R-41236, R-41344, and R-41620 under parser. Their bodies describe a one-day move, June-only offsets, delivery before booking, or differences

between Lisbon and Toronto. The classifier does not establish their root cause. Keep these IDs visible within the parser count and investigate raw booking, timezone, and delivery evidence before asserting a third cause or subtracting them from the classified total. Do not silently relabel them as confirmed month/day swaps.

What the timeline measures

The bars distinguish receipt time from merge time. A merge spike is desk activity, not necessarily a spike in new failures. The chart ends at the export boundary and cannot prove the current queue is stable or fixed.

Replace the triage rule, not its history

The accepted decision 0001 and triage page tell the desk to merge matching subjects. The running demonstration instead compares causes. Matching words are not evidence of a shared cause; different words can describe the same cause. Preserve the accepted record unchanged and propose a new decision superseding subject-only merging with tenant/form/channel evidence and explicit review of unmatched symptoms.

Booking on the wrong date

`parser`

different causes — keep apart

case	same subject	same cause
app vs email, same tenant	no	yes
same subject, same tenant, different channel	yes	no
same subject, same channel, different tenant	yes	no
different subject, same way in	no	yes

case	same subject	same cause
no tenant on file	yes	no

Scope and provenance

This review uses the support-kb export dated 2026-10-04: reports-4471.json, the tenant directory, desk-notes.json, causes.ts, and the existing computed components. The desk continues to work. Refresh its evidence before treating this snapshot as current. No fix has been deployed or verified by this review.
